

POWER BAROMETER

2024

ZEROING IN

Foreword

European Union is steadfast in its commitment to a sustainable future, with ambitious climate targets having been set for the coming decades. Aiming for net zero emissions by 2050, with an intermediate goal of 55% emissions reduction by 2030, the EU's path towards decarbonisation rests critically upon the adoption of clean energy and the development of a robust grid infrastructure.

Within this context, Power Barometer 2024 provides a comprehensive review of the progress that has been made over the past five years, and especially on the developments within this past year. Let's start with the good news. Encouragingly, there has been notable progress in reducing emissions, with the power sector emerging as a leading force in this transition. Last year, nearly two-thirds of the EU's electricity came from clean and renewable energy sources, with nuclear contributing 23% and renewables 45%. Year-to-date in 2024, this share has further increased to nearly three-quarters.

However, despite these positive trends, several challenges persist. The most pressing issue we have observed is the stagnation of electricity demand. Electrification has reached a plateau, and electricity demand growth has stagnated. Although this is partially due to an increase in electrical efficiency, the primary driver is the decline in industrial demand, driven by economic slowdown. Furthermore, the occurrence of negative prices in energy markets is creating a discouraging signal for future investments in renewables, potentially undermining the financial incentives necessary for continued progress. On the other side, the increasing occurrence of negative prices can also be seen as a business case for storage and flexibility resources. Additionally, grid development is something the EU must continue to focus on, along with the development of renewables; both must go hand in hand.

Thus, Power Barometer 2024 aims at providing a clear picture of where we stand today, the progress made, and the obstacles we must overcome to ensure a sustainable and secure energy future for Europe. We hope that Power Barometer 2024 will contribute to the EU energy landscape by effectively informing policymakers and other stakeholders about the energy transition, and on the critical challenge of stagnating electricity demand and electrification.

Kristian Ruby

Secretary General Eurelectric

About

Power Barometer is Eurelectric's annual flagship data report that offers an evidence-based analysis of the EU power sector's performance and its intersection with broader energy issues over the past year. It provides a comprehensive overview of key metrics and progress indicators in the areas of decarbonisation and electrification. By examining the shift towards renewable energy sources, the integration of electricity in various sectors like transportation and industry, and the advancements in grid development, Power Barometer presents a clear picture of the sector's evolution towards a more sustainable and efficient energy system.

Beyond the power sector, the report also addresses critical issues such as security of supply, international competition, and climate change, recognising the integral role of electrification in achieving decarbonisation goals. It delves into market developments and investment patterns, providing stakeholders with crucial insights for navigating today's rapidly changing landscape.

Eurelectric's Power Barometer does not adhere to a fixed list of indicators or metrics. Instead, it adapts its analysis to reflect the latest developments and trends in the energy landscape. This flexible approach ensures that the report remains relevant and provides timely insights into the evolving challenges and opportunities within the electricity sector and beyond.

As the sixth edition of Power Barometer, the 2024 report not only examines the events of 2023 and the ongoing year but also provides a comprehensive progress report of the past five years. This retrospective analysis comes at a critical time as the EU prepares to welcome a new European Commission and offers timely insights into the sector's advancements and challenges over the recent years.

EU's green energy roller coaster: from Green Deal to Repower EU

Our Potential

The EU is a world leader in the green transition and has a well interconnected internal market

Europe is a leader in the green transition

China is increasing its numbers

by taking advantage of its large population and material resources.

Leader in newly-installed capacity and investment in renewables

60% of global net-zero technology manufacturing

>50% electric vehicles drive on Chinese roads

European Union is increasing its share

and strives to integrate the most renewables within its population

Highest share of renewable electricity generation

Leader in investment and deployment of heat pumps

Highest use of electric vehicles per capita

Source: Strategic perspective report "Competing in the new zero-carbon industrial era"

Using EUs natural strengths to decarbonise

EU has some of the best wind and solar resources

EU uses them to produce green electricity

Spread within EU Single Internal Electricity Market

Wind speed (m/s) in 10% windiest area in 2024

Average daily sunshine hours in 2024

■ Variation ● Average

220 GW

490 TWh

Second largest wind power capacity and wind electricity production

263 GW

237 TWh

Second largest solar power capacity and solar electricity production

420 interconnections

445 TWh of cross-border electricity flow

Highest electricity traded in power exchanges

Power Sector Progress Report

Power Sector Progress Report

Decarbonisation

The power sector is leading the EU's decarbonisation

Power sector's emissions dropped by 50% between 2008-2023

The power sector's emissions & emissions intensity dropped significantly in 2023 compared to the previous year. Some of this will be permanent as more and more renewable capacity enters the grid. A portion of the drop can be attributed to the slowdown of industrial demand. 2024 is poised to see further emission reductions.

2024 is seeing a further drop in emissions compared to 2023

gCO₂/kWh

* Carbon neutral

Rising share of clean electricity in the EU: 74% in 2024 YTD

In 2023, renewables surged to a historic 45% share of the EU's electricity mix, led by wind energy at 18%. This marked the first time wind surpassed natural gas in power generation

In 2023, 68% of the EU's electricity in the EU came from renewable and nuclear sources. In 2024 YTD, this has increased to 74%, with 50% now coming from renewables

Source: Eurelectric's [Elda](#), Eurostat for 2015

Clean power surges while fossil fuels decline to lowest share on record

EU Electricity Generation Shift: 2022 vs 2023

Electricity generation decreased overall due to reduced demand. Fossil fuel generation dropped by 393 TWh, while low-carbon power increased by 160 TWh, resulting in the lowest fossil fuel share on record

Reduced demand and additional installed renewables capacity contributed to this transition

Source: Eurelectric's [Elda](#).

Expected 70% renewables by 2030

Power Sector Progress Report

Power Prices

Power prices have decreased and are now below pre-war levels

Volatile power prices: the need for more renewables & flexibility

Electricity prices tend to follow gas prices, which have shown volatility. The recent energy crisis underscores the urgent need for extensive adoption of renewables and greater system flexibility. Swift implementation of the electricity market reform, including long-term contracting and enhanced system flexibility, would better safeguard consumers from short-term price fluctuations.

Power Generation Infrastructure

Installed capacity is growing with a record number of renewables

Solar PV installations surge while wind energy falls below targets

Annually installed wind and solar PV in the EU

Source: Wind Europe, Solar Power Europe, Eurelectric

🔋 Solar PV installation in 2023, +3.3X from 2019

56 GW of solar PV were installed in 2023 compared to 16.7 GW in 2019.

🔋 Wind installation in 2023, +1.5X from 2019

Wind installation grew in 2023, but this growth represented only half of what's needed to meet the 2030 target.

🔋 Bottlenecks

Permitting, grid infrastructure, supply chain constraints and challenging financing conditions remain bottlenecks for increasing renewables. Specifically, grid integration taking up to 8 years for solar and 10 years for wind are big challenges.

All technologies needed for the transition

56 GW of solar PV and 16 GW of wind were installed in 2023. This represents a 300% and 150% growth in solar and wind installations respectively compared to 2019

Along with renewables, other clean, firm and flexible technologies are needed for the transition

Flexibility becoming increasingly important

The cost of redispatch has increased since 2019 and is becoming more influenced by seasonal variations

Source: ENTSOE transparency platform, ACER

Increase in cost of capital represents a challenge

Long-term interest rate (10-years maturity) in the Euro area

- Rising base rates have driven up the cost of debt in the last two years, creating a difficult environment for the renewables financing community to navigate
- In Europe, this has caused the levelised cost of electricity (LCOE) of offshore wind to rise in 2023
- Some offshore wind projects were paused to re-evaluate investment strategies

Source: ECB, Pexa Park

Mixed outcomes for Europe's wind energy development

>2X

Investment in wind energy

Despite tighter financing conditions, investments into Europe's wind energy more than doubled in 2023 compared to 2022, reaching a value of €48 billion; €30 billion of which went to offshore projects while the remaining €18 billion went to onshore projects.

+70 %

2023 vs. 2022: Permitted wind capacity in Germany & Spain

Germany and Spain permitted 7.5 GW and 3 GW respectively in 2023, 70% more than in 2022. Improvements were also visible in other markets such as France (+12 %), the UK (+10 %), Greece and Belgium.

3.3 GW

Undersubscribed onshore wind in Germany

In 2023, only 6.5 GW out of the 9.8 GW auctioned onshore wind capacity received bids in Germany. Spain held no auctions in 2023 after a 6% subscription in 2022. France and Italy saw oversubscription in 2023, unlike in 2022.

0 GW

Offshore wind in UK auctions

There were no offshore wind project bids during the UK's 5th CfD auction because auction parameters – especially strike prices – had not kept up with rising project costs – a problem that could jeopardize the 2030 offshore wind target.

Power Sector Progress Report

The background of the slide is a composite image. On the left, there is a digital display showing various numbers in green and red, some with plus and minus signs, resembling a stock market ticker. In the center and right, there is a candlestick chart with yellow and orange bars. In the foreground on the right, there is a pile of coins, some of which are stacked.

Markets and Investments

A mix of positive and concerning signals from the market

Negative prices on the rise: the need for flexibility

Number of hours where at least one EU27 country had a negative price

Evolution of negative price occurrences throughout the year in at least one bidding zone (BZ)

Number of hours with negative prices surged in 2023 & 2024 compared to previous years

While in 2023 there were negative prices during 9% of the total hours, from January to August 2024, this already increased to 18% as the EU recorded 1031 hours of negative prices in one or more of its BZs

Source: Eurelectric's Elda and calculations

Are negative prices occurring simultaneously in multiple bidding zones?

Distribution of negative price occurrences across multiple bidding zones

While in 2022 there were 249 hours with negative prices in at least one EU BZ, this rose to 821 hours for 2023. As of August 2024, the hours have already increased to 1031 hours. Zooming in on the 2024 data, there has been 499 hours where 5 or more BZs experienced negative prices simultaneously, whereas in 2023 the same took place for a total of 414 hours.

Source: Eurelectric's Elda and calculations

Solar driving negative prices in 2024

Most negative price hours occur at times of peak solar power generation

The capture rate for an asset measures how much of the average wholesale price an asset earns as revenue. In Spain, the capture rate for solar PV dropped to a low of 41% in April 2024. This indicates that solar PV was a major driver of negative prices.

This underscores the need for system flexibility, electrification and well-designed support schemes amidst increasing renewable energy integration.

Source: Eurelectric's Elda and calculations

Occurrence of negative prices 2023: Member State perspective

The arrival of new nuclear power plants, together with increased wind and solar generation, triggered more negative price occurrences in Finland. Meanwhile, Spain and Portugal saw negative prices for first time in 2024.

Source: Eurelectric's Elda

Occurrence of negative prices 2024: Member State perspective

Occurrence & depth of negative prices – 2023 & 2024

Number of negative price hours & average depth of negative prices in European bidding zones in 2023

Number of negative price hours & average depth of negative prices in European bidding zones in 2024

Tip for reading the graph:

The farther right and higher a country appears, the more frequent and severe its negative prices.

In 2023 and 2024, the Netherlands saw frequent and deep negative electricity prices due to rising renewables, grid congestion, and insufficient flexible power sources. While the Nordic countries had more negative prices, their depth was lower than in Central Western Europe (CWE) and Southeastern Europe (SEE)

Various factors can cause negative prices

Country	Major driver of negative price
Netherlands (NL)	High solar, High wind, Low demand
Austria (AT)	Imports, Low demand
Germany (DE)	High solar, High wind, Imports, Low demand
Czech Republic (CZ)	Imports, Low demand
Hungary (HU)	High solar, Imports, Low demand
Great Britain (GB)	High wind, Low demand
Denmark (DK1)	High wind, Imports, Low demand
France (FR)	High solar, High wind, Imports, Low demand
Denmark (DK2)	High wind, Imports, GOs, Low demand
Finland (FI)	High must-run generation, High wind, Low demand
Norway (NO2)	GOs, Imports, Low demand
Sweden (SE4)	GOs, High solar, High wind, Imports, Low demand
Sweden (SE1)	GOs, High wind, Low demand
Norway (NO4)	GOs, Low demand
Spain (ES)	GOs, Low demand
Portugal (PT)	Imports, Low demand
Greece (GR)	Imports, Low demand

1. PM is project management

Source: Eurelectric Grids4speed

Implication for distribution grid strategy

- Electricity grid projects are dominated by fixed costs for electrical installation and civil works, along with permitting, engineering and project management costs. Only material and equipment component costs are variable, as these are determined by the electrical size or capacity of the project.
- Typically, increasing the capacity of a grid project (e.g., line, cable or transformer installation) will only increase the cost of the project marginally, if within the same voltage level. For instance, doubling capacity may increase costs by around 10% to 20%, yet provide additional capacity for planned future projects, such as renewables integration, new housing developments or heat electrification.
- Where future strong load growth is likely, it may be prudent to strategically size up capacity as an anticipatory investment during reinforcement or replacement projects. This will reduce the investment required in demand and generation-driven reinforcement as additional capacity is available.

Iron & Steel industry is the major outlier, where full electrification is technically not feasible with 200 TWh demand for a reducing agent

Source: Agora Industry

Three case studies for industry electrification

Iron & steel:

Steel rolling is used to shape raw steel into flat and long steel products, which are then turned into finished goods. Today, the fossil fuel demand for steel rolling in the EU is roughly 2.0 GJ/t, while the electricity demand is 0.4 GJ/t (Fleiter et al. 2023b).

Electric solution:

In July 2024, SSAB and Danieli have signed an Early Service Agreement for the Luleå mini-mill project in Sweden. Danieli will supply a highly-automated technology solution for the new mini-mill, consisting of two electric arc furnaces, secondary metallurgy, caster and strip mill. Quality hot-rolled coils will be produced through electric steelmaking and direct casting-rolling.

Chemical:

Steam cracking is used to produce ethylene and other high-value chemicals (HVCs). Naphtha or gaseous hydrocarbons are mixed with superheated steam and cracked at temperatures above 800°C with a process heat demand of 35.9 GJ/t (Fleiter et al. 2013).

Electric solution:

In a major milestone for the sector, BASF, Sabic and Linde commissioned the world's first electric cracker demonstration project in Germany in April 2024. The electrified steam crackers employ resistance and shock-wave heating. With electrification, the efficiency of these steam crackers is expected to be as high as 95%, versus the 40% efficiency of today's fuel-based steam crackers (Jasi 2023).

Non-ferrous metals:

Non-ferrous metals processing includes aluminium melting, aluminium homogenising, aluminium heat treatment, copper melting and others. While electricity already accounts for a large proportion of the energy used by the non-ferrous metals sector, a large proportion, 36%, of the remaining fossil fuel use supplies temperatures below 500°C and could therefore be easily electrified.

Electric solution:

Even at high temperatures, induction and resistance heating offer efficient alternatives to fuel-based heating. As an example, in February 2024, major Romanian aluminium smelter Alro's Wrought Aluminum invested in an electric furnace for its production of primary aluminium.

Electricity prices twice higher than gas in 2023, especially for industry

Electricity/gas retail prices ratio
for household consumers in 2023

Electricity/gas retail prices ratio
for industry in 2023

- When looking at the ratio of electricity to gas prices, on average, both household and industry electricity prices were twice as high as gas prices in the EU27 throughout 2023
- Overall, the difference between electricity and gas prices is greater for industry than for households
- On average, electricity is more efficient for producing heat than gas

Prices excluding VAT and other recoverable taxes

Source: Eurostat, Eurelectric

Taxes still contribute significantly to the price difference

Electricity is taxed 1.4 times more than gas, resulting in higher prices

Source: Eurostat

Electrons are more efficient than molecules

Current share of clean and fossil energy in H2 and electricity in the EU (%)

Electricity required to run an EV and FCEV for 100 km (kWh)

Share of renewables in today's major energy vectors (%)

Electricity consumption required to space heat an average EU household (kWh)*

Source: Eurelectric calculations based on Eurostat,

For heating, average household consumption considered 11875 kWh, COP for heat pump assumed to be 3.5 and efficiency of hydrogen boiler starting from electricity to hydrogen to heat assumed to be 65 %. For FCEV vs EV comparison, the electricity is assumed to be grid electricity.

GLOBAL CHALLENGES

Global Challenges

Manufacturing and Supply Chains

The EU needs to find the right balance to supply its growing demand for clean technology

Risky supply chain for wind

Wind turbine demand and manufacturing capacity in Europe

Europe boasts one of the world's largest wind power component manufacturing capacities with a well interconnected supply chain

Demand is expected to outpace the turbine supply by 2026

Current European manufacturing capacity exceeds the annual wind turbine demand in Europe

Plans for expanding capacity are needed if the demand is to be met by European supply

Source: Wind Europe

EU battery manufacturing capacity must grow

EU battery manufacturing met only 27% of the e-mobility sector's demand in 2021

92% of the final energy demand from industries can be electrified with current technology

Given announced projects, capacity will reach between 714-1200 GWh by 2030. However, several challenges remain, like attractive incentives in other economies and delays in said projects

Transformer shortage could cause grid bottleneck

Copper prices (2019-2024)

Transformers use high quality copper. Copper prices have more than doubled in the past 5 years due to a high demand and stagnant supply. Copper represents around 14% of DSO investments.

2070

Out of the top 5 emitters, the EU leads in the quest for achieving net zero

US faces a potentially risky political situation that could jeopardize its path to net zero

China and India, the growing emitters, continue to build coal power plants

Policy Recommendations

Policy recommendations

The power sector has made significant strides towards decarbonisation over the past year, achieving a 50% reduction of emissions between 2008 and 2023. The market is functioning effectively and has strong fundamentals. Moving forward, our focus must shift to the following policy recommendations:

01

Ramping up electrification as quickly as possible. The slow down in electricity demand, and especially of industrial electricity demand, should be addressed by easing the economic barriers. An electrification action plan should be created to showcase the true value of electricity.

03

Grid infrastructure development should be facilitated by modernising grid tariffs and ensuring access to EU funds. Forward-looking grid strategies such as anticipatory investments, optimal asset management and grid-friendly flexibility should be implemented.

02

Stimulate growth in **flexible and storage technologies**. The role of flexibility in the energy system should be duly recognised. This flexibility can come from either the demand side, from generation assets, energy storage and/or electrolyzers. An energy storage strategy is needed to stimulate storage investment.

04

Industrial competitiveness should be fostered through an industrial complement to the EU Green Deal, as well as competitively priced electricity and a swift implementation of the EMD.
